The Puzzle of Hypertension in African-Americans

by Richard S. Cooper, Charles N. Rotimi and Ryk Ward

Nearly all Americans undergo a steady rise in blood pressure with age. Almost 25 percent cross the line into hypertension, the technical term for chronically high blood pressure. This condition, in turn, can already contribute to heart disease, stroke and kidney failure and thus plays a part in some 500,000 deaths every year. For black Americans, the situation is even more dire: 33 percent suffer from hypertension. Worse, the ailment is particularly deadly in this population.

Frustrating Search for Hypertension Genes Continues

By Edward R. Winstead

July 11, 2003

Despite years of searching, researchers have yet to discover a human gene that controls blood pressure or contributes to hypertension. The worldwide effort has generated a list of chromosome regions that may contain these genes but no specific genes or variants.

Now, a region of chromosome 6 has been added to the list. British researchers discovered the region by "scanning" the genomes of 2,000 pairs of siblings from families with severe hypertension for DNA they had in common. In addition to chromosome 6, several other areas were implicated, but the statistical evidence was modest.

The next step is to screen the regions for gene candidates, but the researchers acknowledge that whatever they find will not be the whole story on the genetics of hypertension.

Indeed, the story seems to be that many genes (or variants) contribute in small degrees to inherited differences in blood pressure, and that different genes may confer risk for hypertension in different populations.

'Where are all the blood-pressure genes?'

"We really don't know how many blood pressure genes there are," says Mark J. Caulfield of Queen Mary's School of Medicine, London, who led the new study. "We hope they number 5 or 10, but there could be 20 or more."

As with other complex diseases, like schizophrenia and heart disease, pinpointing genetic risk factors for hypertension will not be easy.

Consider a recent analysis of data from genome scans for hypertension genes published in the scientific literature. This "meta-analysis" found that no single chromosome region consistently had large effects on blood pressure or hypertension in all the study populations. It was published in the *American Journal of Hypertension* in February.

The original genome scans were done at medical centers in the United States as part of the National Heart, Lung, and Blood Institute Family Blood Pressure Program (FBPP). The subjects came from different ethnic groups and represented the racial diversity of the U.S. population.

The new research is part of the Medical Research Council's BRItish Genetics of HyperTension (BRIGHT) study. The findings appear in *The Lancet* along with a commentary entitled "Where are all the blood-pressure genes?"

Citing the challenges of finding genes underlying common diseases, the commentary's author, Stephen B. Harrap of the University of Melbourne, Australia, suggests that it simply may not be possible to discover gene variants for hypertension that would be valuable in the diagnosis of the disease.

Rather than search for every gene variant underlying hypertension, he argues, the field needs to "search for molecular clues to the common physiological mechanisms underlying disease."

The study in *The Lancet* may ultimately lead to new risk factors for severe hypertension. None of the chromosome regions in the study was associated with the disease in humans until now. But part of chromosome 2 corresponds to a region of the rat genome associated with elevated blood pressure.

"We are encouraged by this because it means we may have found a region that actually contains genes" for hypertension, says Caulfield. "We're making some progress, though perhaps not as much as we would like."

"If finding the genes were easy, we would not have undertaken such large studies."

...

Caulfield, M. *et al.* Genome-wide mapping of human loci for essential hypertension. *Lancet* **361**, 2118-2123 (June 21, 2003).

Harrap, S.B. Where are all the blood-pressure genes? *Lancet* **361**, 2149-2151 (June 21, 2003).

Province, M.A. *et al.* A meta-analysis of genome-wide linkage scans for hypertension: The National Heart, Lung and Blood Institute Family Blood Pressure Program. *American Journal of Hypertension* **16**, 144-147 (February 2003).

Indeed, the story seems to be that many genes (or variants) contribute in small degrees to inherited differences in blood pressure, and that different genes may confer risk for hypertension in different populations

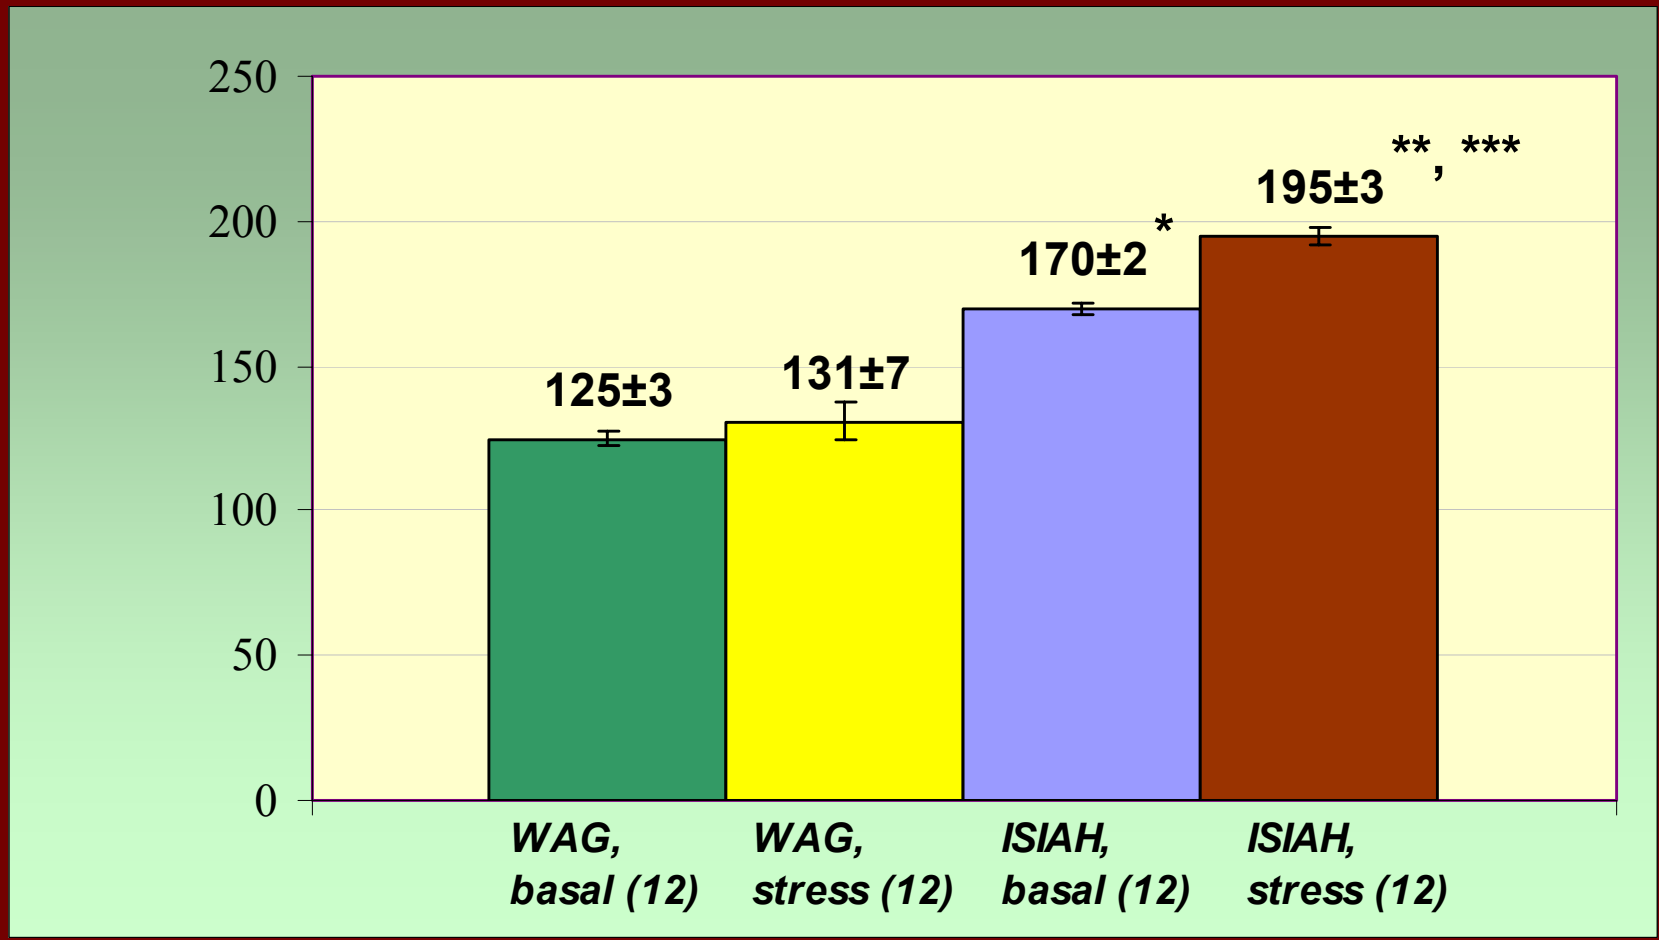
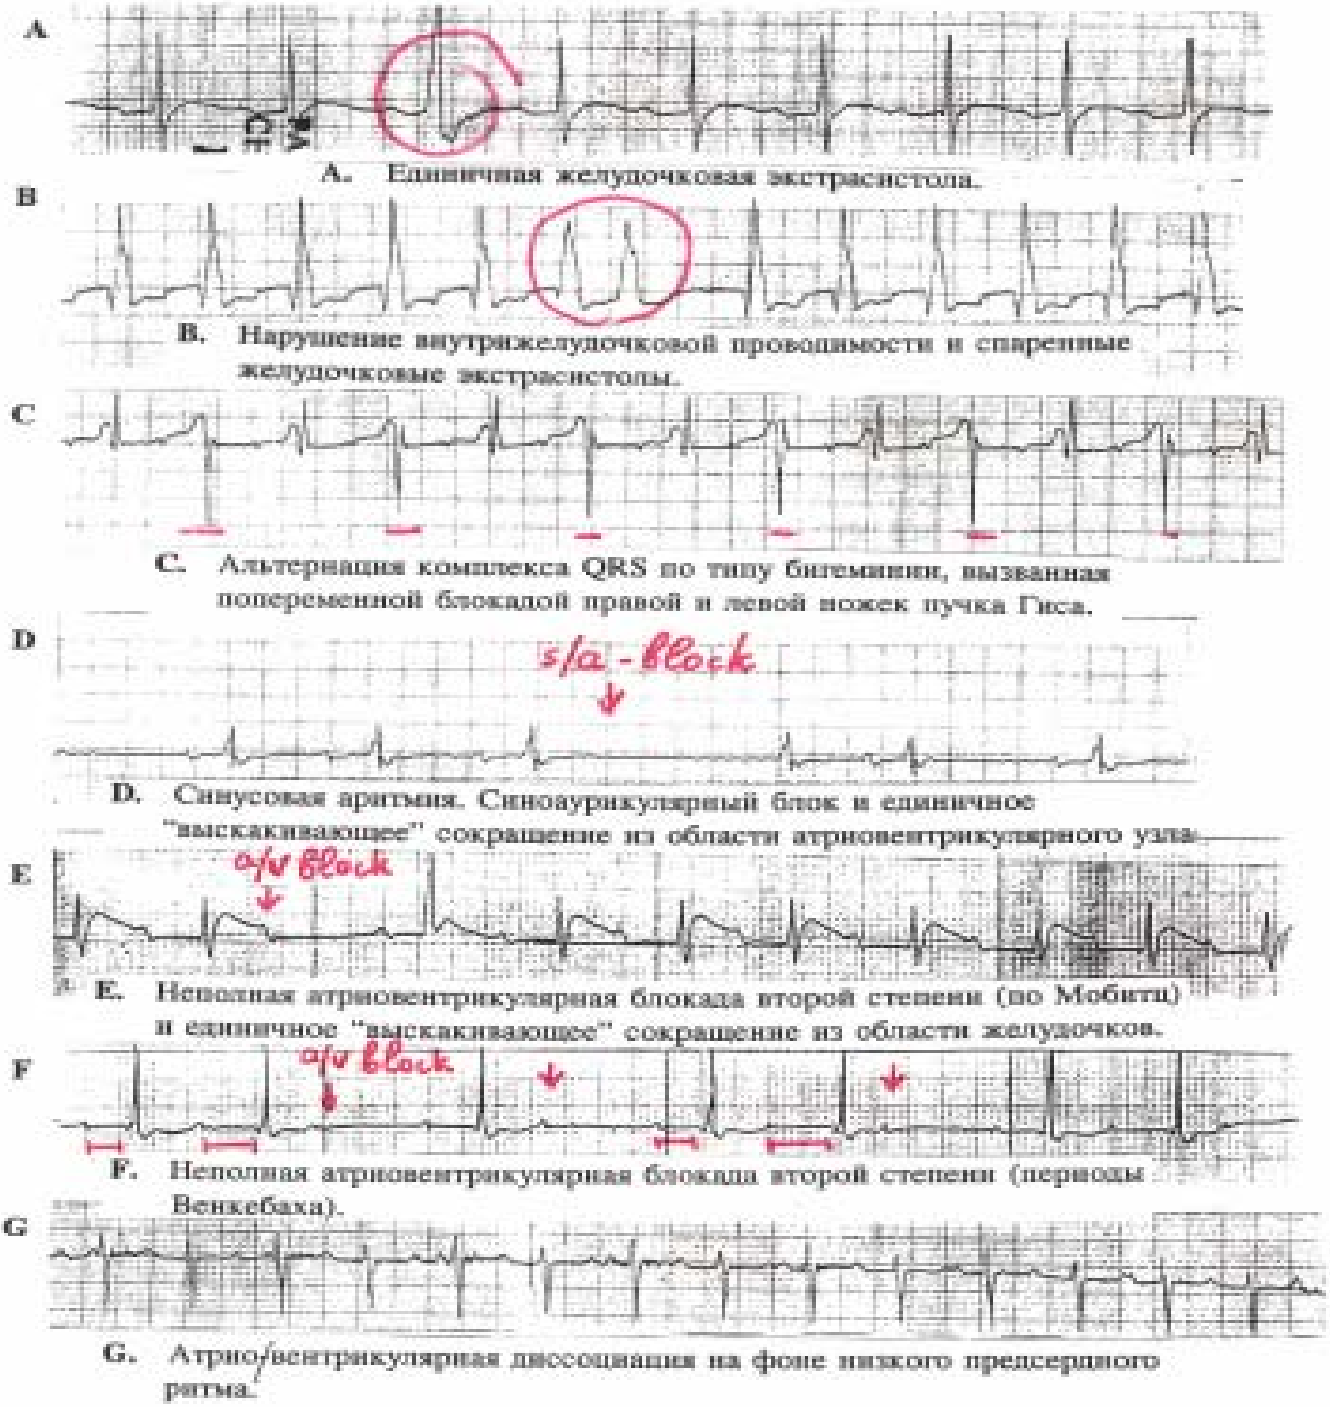
Basal and stress-induced BP levels in WAG and ISIAH rat strains





A. Единичная желудочковая экстрасистола.

B. Нарушение внутрижелудочковой проводимости и спаренные желудочковые экстрасистолы.

C. Альтернация комплекса QRS по типу бигеминии, вызванная попеременной блокадой правой и левой ножек пучка Гиса.

D. Синусовая аритмия. Синоаурикулярный блок и единичное "выскакивающее" сокращение из области атриовентрикулярного узла.

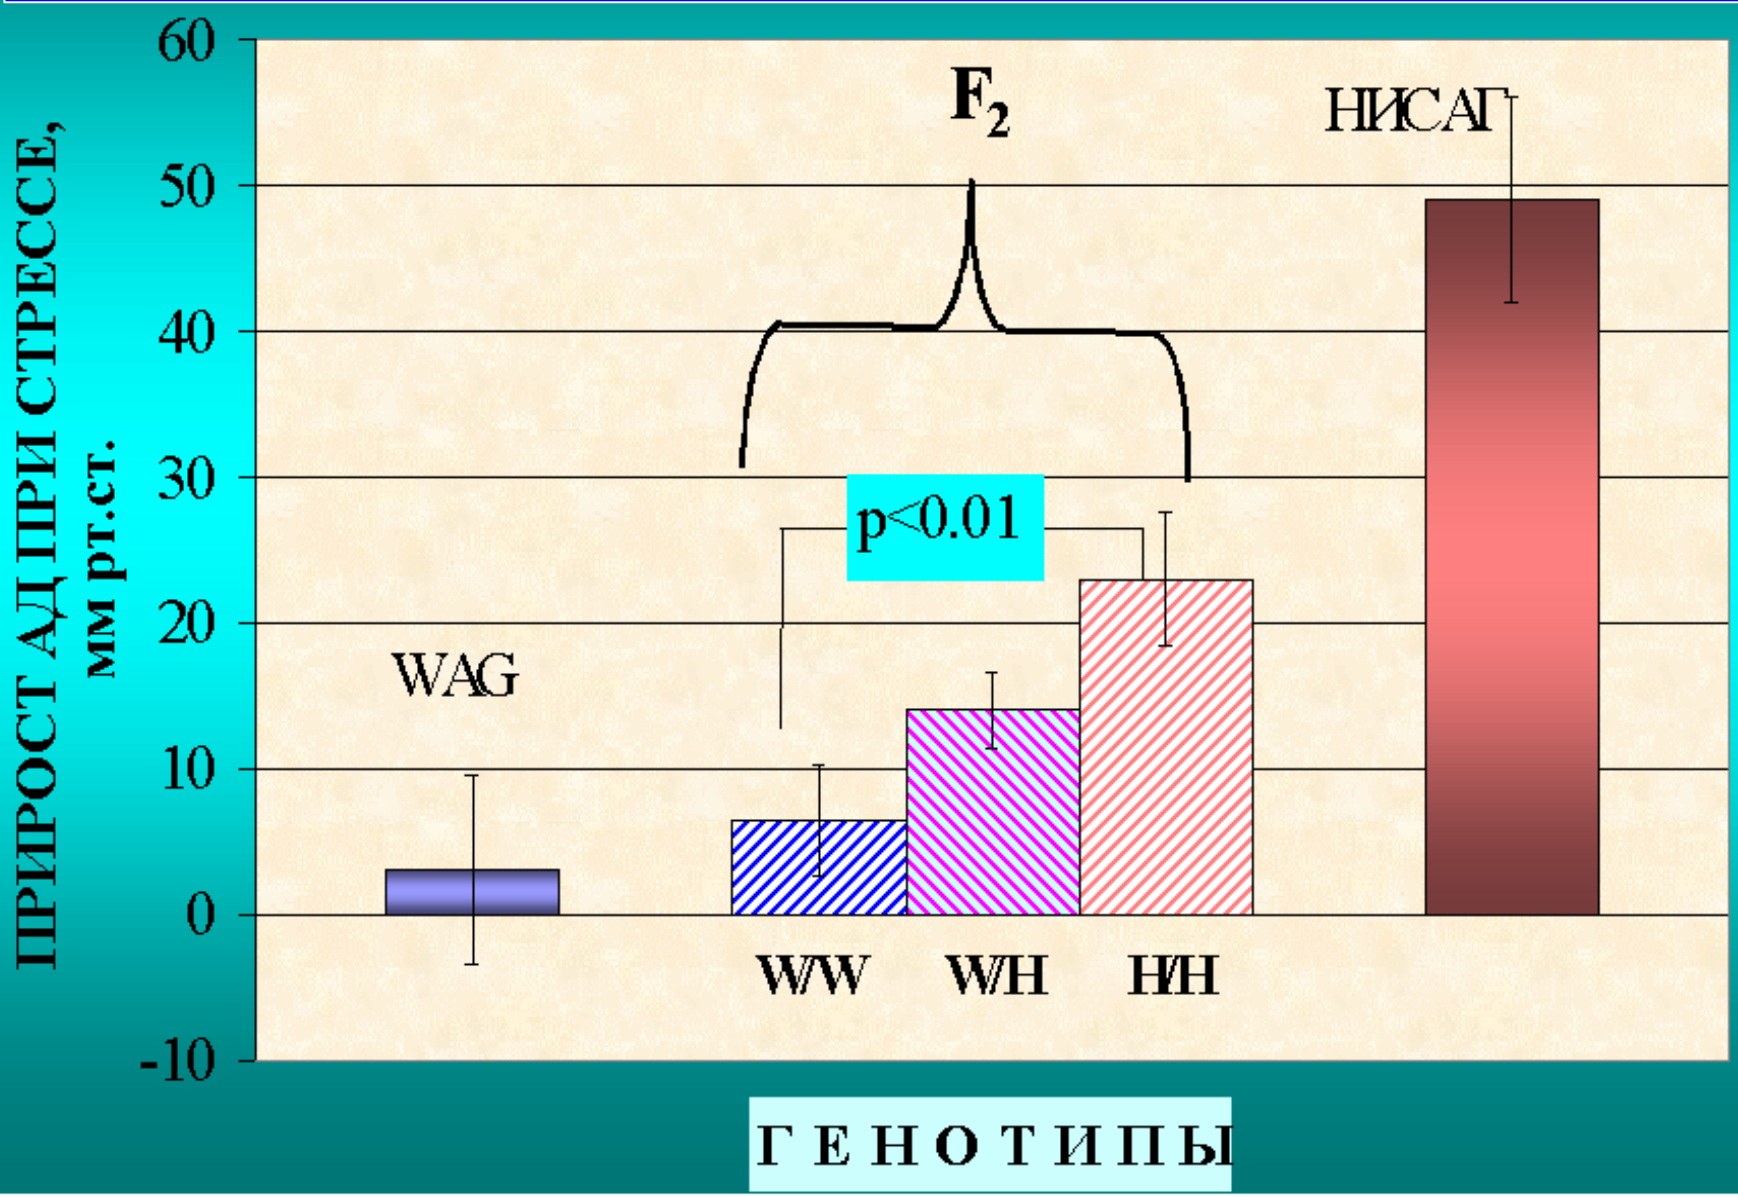
E. Неполная атриовентрикулярная блокада второй степени (по Мобитц) и единичное "выскакивающее" сокращение из области желудочков.

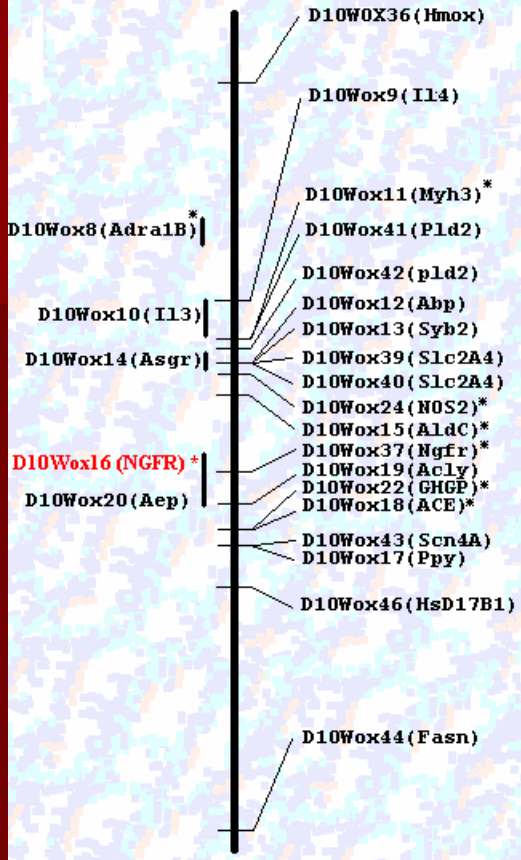
F. Неполная атриовентрикулярная блокада второй степени (периоды Венкебаха).

G. Атрио/вентрикулярная диссоциация на фоне низкого предсердного ритма.

Нарушения сердечного ритма у крыс линии НИСАГ по данным ЭКГ исследо-вания

Локус *NGFR* и величина прироста АД при стрессе





Hmox - гем оксигеназа 2
Il4 - интерлейкин 4
Myh3 - эмбриональный миозин, тяжелая цепь
Adra1B- альфа 1 В-адренергический рецептор
Pld2 - фосфолипаза D
Abp - андроген-связывающий белок
Il3 - интерлейкин 3
Syb2 - синаптобревин 2
Asgr - асиалогликопротеиновый рецептор
Slc2A4- переносчик глюкозы 4
NOS2 - индуцибельная NO-синтаза
AldC - альдолаза С
Ngfr - рецептор фактора роста нервов
Acly - АТФ-цитрат лиаза
Aep - анион-обменный канал
GHGP - гормон роста
ACE - ангиотензин превращающий фермент
Scn4A - альфа субъединица потенциал-зависимого натриевого канала
Ppy - панкреатический пептид
Hsd17B1- гидроксистероид дегидрогеназа 17 бета
Fasn - синтаза жирных кислот

Звездочкой (*)обозначены локусы генов-кандидатов, для который была найдена ассоциация с гипертонией у человека или на какой-либо из моделей экспериментальных животных

come first of all to the Sirens, who are enchanters of a
whoever comes their way: and that man who un
proaches them, and listens to the Sirens singing, has
coming home. You must drive straight on past. . .
Homer

faced with the Sirens. The song we hear is all the more seductive because it originates deep within ourselves. Nevertheless, our roles as physicians and as guardians of the public trust dictate that we do all we can to resist the temptation to jump into human studies until we have gathered overwhelming evidence for both safety and efficacy. For the

The prospect of using genes as therap presents myriad opportunities. No physic to appreciate the power of this approa abandon the shackles of the limited pharmac device repertoire and focus instead on reeng culprit tissue by somatic gene transfer? The genomic information leaves us with an emba riches in terms of potential therapeutic agents. V line at nature's own genes expressed in their u Genes can readily be tailored to exhibit special found in nature, altering the function of their protein products for specific ends. Alternatively, wild-type genes can be expressed in tissues where they are normally silent.

See p 1578

In this issue, Weig et al[1] describe a clever application of the latter approach: V2 vasopressin receptor genes, usually expressed only in kidney, were delivered to myocardium packaged in recombinant adenoviruses. Expression of these adenyl cyclase–activating receptors in the myocardium converted the basal negative inotropic response to infused vasopressin into a positive one. Because vasopressin levels are elevated in heart failure, a situation in which β-receptors are uncoupled from cyclase,[2] ectopic expression of V2 receptors would logically be predicted to recruit cAMP-mediated contractility in failing myocardium while bypassing the desensitized β-adrenergic pathway. The work has conceptual beauty. It also presents 2 important methodological innovations: first, the use of in situ viral transduction followed by myocyte isolation to enable careful phenotypic characterization of genetically altered cells; second, the adaptation for in vivo use of previously described strategies for optimizing transcor-

Korotkov sounds – what do we know about this 100 year old discovery?

Nikolai Sergeievich Korotkov (1874–1920)

This year, 2005, is the 100th anniversary of one of the most famous discoveries in the field of hypertension: the auscultative method of blood pressure measurement. The method, named after the Russian physician and scientist Nikolai Sergeievich Korotkov (1874–1920), has now been widely used for one century. Unfortunately, while the method itself and the name of its inventor are world famous, much less is known about the history of this outstanding discovery and the real role of Korotkov in the interpretation of the discovered sounds and the implementation of the new method into clinical practice.

Korotkov was only 31 years of age when he made a short presentation at the Scientific Meeting of the Military Hospital of the Imperial Military Academy about an easy, non-invasive method of blood pressure measurement. This was on November 5, 1905. The brief title of his presentation was "Concerning the problem of the methods for investigating blood pressure". He described the following sequence of sounds: first sound, ten murmurs, loud sounds, decreasing sounds and complete disappearance. These observations are now classified as different phases of the Korotkov sounds. Later, Russian scientists and investigators all over the world continued to find an explanation for the auscultative phenomenon. Although our modern understanding of the nature of the sounds has changed, the method remains the standard for hypertension diagnosis and management. Even today, 100 years later, devices are being devel-

Report from the 6th International Symposium on Hypertension and Related Diseases from October 15–18, 2004 in Beijing, China

On the occasion of this Symposium, the World Hypertension League (WHL) held a Regional Meeting on the Prevention of Hypertension. It was chaired by Prof. Liu Lisheng, Vice President of the WHL, Prof. Zhou Beifan, and Dr. Claude Lenfant, President of the WHL. There were 8 presentations describing research and public health activities in the respective countries.

Dr. Lenfant summarized 4 studies from the United States which exemplify the significance and effectiveness of programs to reduce excess weight, to encourage physical exercise, and to reduce salt and alcohol consumption to maintain, or reduce blood pressure (BP) to a normal level (i.e. <140/85 mmHg). He noted that to control hypertension we have the choice between pharmacological and preventive interventions: he concluded that preventive interventions are effective and far less costly than pharmacological regimens.

WORLD HYPERTENSION DAY May 14, 2005

Initiated by the World Hypertension League

Saturday, May 14, 2005

The objectives of the **World Hypertension League** are to promote the detection, control and prevention of arterial hypertension in populations. Bringing together and stimulating organizations committed to the control of hypertension is the goal and the raison d'être of the WHL.

HYPERTENSION - THE SILENT KILLER

KNOW YOUR BLOOD PRESSURE

GENERAL RULES FOR BLOOD PRESSURE MEASUREMENT

- Rest for 5 minutes before measurement
- Refrain from smoking or ingesting caffeine for 30 minutes prior to measurement
- Be seated with feet flat on the floor, back and arm supported, and arm at heart level
- Use appropriate sized cuff
- Use recently validated device
- An average of two or more readings should be taken, at least two minutes apart

Under special circumstances measuring blood pressure in standing and supine positions may be indicated.

For further information see the WHL website at www.worldhypertensionleague.org

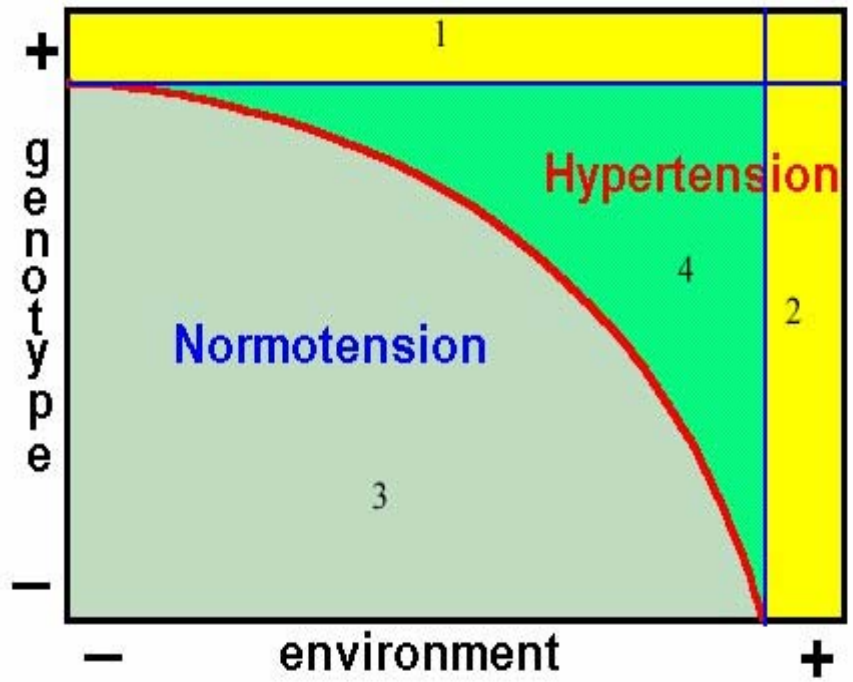
GENOTYPE-ENVIRONMENT INTERACTION IN HYPERTENSION DEVELOPMENT



1 - Genotype-dependent hypertension

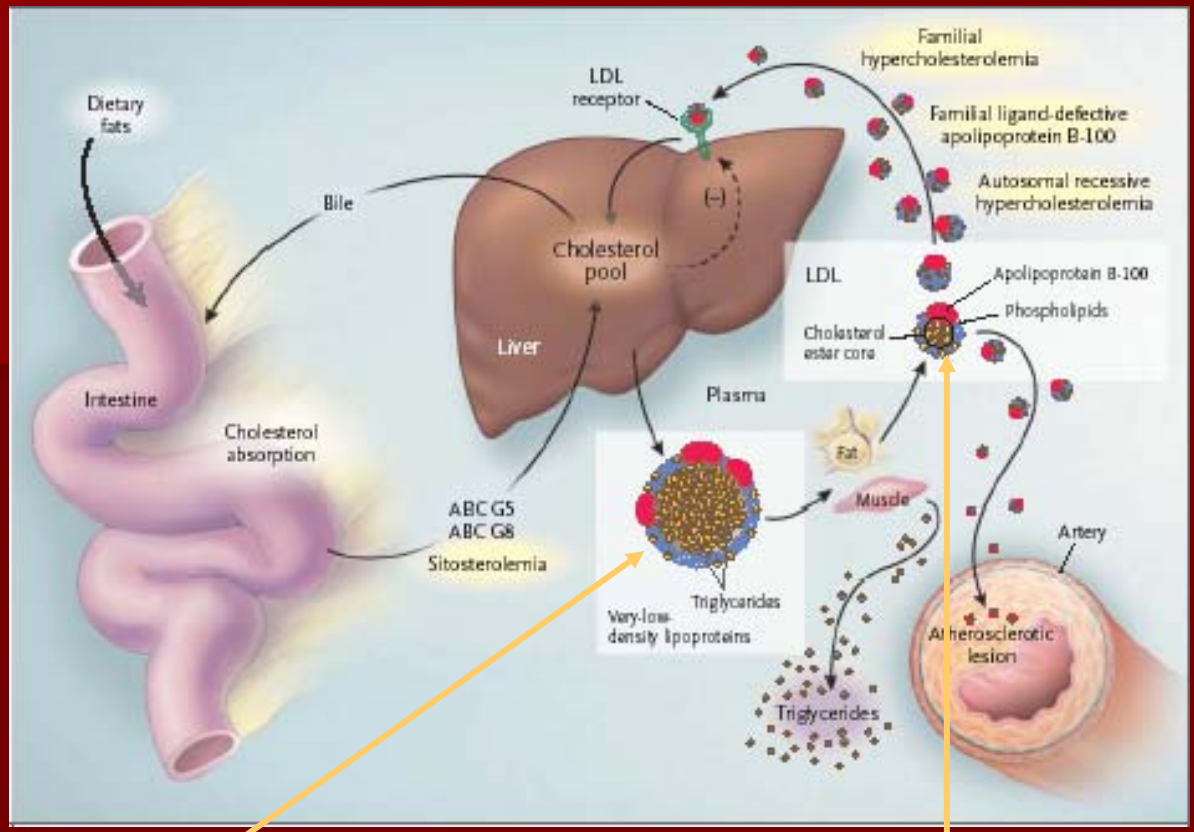
2 - Environment-dependent hypertension

3 - Normotension

4 - Hypertension dependent on genotype-environment interaction

+ -"Hypertensive" genes or environments

- - "Normotensive" genes or environments



Печень секретирует липопротеины очень низкой плотности, включающие эфиры холестерина и триглицериды в оболочке из фосфолипидов и аполипопротеина B-100

Липопротеин низкой плотности (LDL) – главный носитель холестерина в плазме крови и один из главных факторов сердечно-сосудистой патологии

НОСИТЕЛИ ХОЛЕСТЕРИНА

Мутации снижающие клиренс холестерина плазмы крови

Семейная гиперхолестеринемия: мутации (>600 вариантов) гена, кодирующего LDLR (гетерозиготы – 1:500, гомозиготы – 1:1 000 000)

Нарушения связывания LDLR с лигандом – APOB-100: нарушен клиренс холестерина плазмы крови вследствие мутаций гена *APOB-100* (гетерозиготы – 1:1000)

Ситостеролемия – нарушение транспорта и абсорбции холестерина в просвет кишечника: мутации генов *ABC G5* и *ABC G8* (встречаются редко) – накопление холестерина в печени и подавление синтеза LDLR

Гиперхолестеринемия: редкая аутосомальная мутация (1:10000000) гена *ARH* приводит к нарушению функции рецептора LDLR
